Import Data using Transform Maps (Spreadsheet)

Phase 05 - Project Development Phase:

Flow Chart:

Prepare Spreadsheet
↓
Create Import Set
↓
Load Spreadsheet Data
↓
Create Transform Map
↓
Configure Field Mappings
↓
Apply Transformations
↓
Run Transform
↓
Validate Imported Records
↓
Fix Errors & Retest
↓
Development Completed

Spreadsheet Preparation:

The first step in the development phase is to prepare the spreadsheet according to the requirements identified in the previous phases. The spreadsheet should contain properly organized columns and valid data. Unnecessary columns should be removed, and values should follow a consistent format. Mandatory information should be checked before uploading the file into ServiceNow.

Creating the Import Set:

After preparing the spreadsheet, an **Import Set** is created in ServiceNow. The Import Set acts as a temporary staging area where the data from the spreadsheet is stored before it is transferred to the final target table. The appropriate import process is configured based on the type of data being uploaded.

Loading Spreadsheet Data:

The prepared spreadsheet is uploaded into the Import Set. ServiceNow reads the spreadsheet columns and creates corresponding source fields in the import table. The uploaded

records are reviewed to make sure that the source data has been loaded correctly without unexpected formatting or missing values.

Creating the Transform Map:

The next step is to create a **Transform Map**. The Transform Map defines how data from the Import Set should be transferred into the target ServiceNow table. The appropriate source table and target table are selected, and the transformation process is configured according to the project requirements.

Configuring Field Mappings:

Field mapping is one of the most important development activities. Each source field from the spreadsheet is mapped to its corresponding target field in ServiceNow. For example, a spreadsheet field such as **Short Description** can be mapped to the Short Description field in the target table. Mandatory and reference fields should receive special attention to ensure that records are created correctly.

Applying Transformation Rules:

Sometimes spreadsheet data cannot be directly inserted into the target table. In such situations, transformation logic is required. Scripts or transformation rules can be used to modify values, convert formats, set default values, or process reference information before the record is created in the target table.

Executing the Transform:

After completing the field mappings and transformation rules, the Transform Map is executed. ServiceNow processes the Import Set records and attempts to create or update records in the target table. The transform results should be monitored carefully to identify successful and failed records.

Testing and Error Handling:

The imported records are then tested against the original spreadsheet data. Field values, mandatory fields, reference fields, and transformation results are verified. If errors are identified, the mapping or transformation logic is corrected and the data is transformed again. This process may be repeated until the expected results are achieved.

Validation and Development Completion:

The final step is to validate the completed import process. The development team confirms that the required records have been created accurately and that the Transform Map performs as expected. Successful test results and configuration details are documented for the next phase.
