Import Data using Transform Maps (Spreadsheet)

Phase 06 - Project Testing Phase:

Flow Chart:

Test Planning:

The Project Testing Phase begins by preparing a proper testing plan for the spreadsheet import process. The main objective is to verify whether the Import Set and Transform Map work according to the requirements defined in the earlier phases. The testing plan identifies the areas that need to be tested, expected results, test data, and validation methods.

Test Data Preparation:

Suitable test data is prepared before executing the import process. The test spreadsheet should contain normal records as well as different data conditions such as missing values, duplicate records, invalid values, and incorrect formats. This helps determine whether the Transform Map can handle different types of input data correctly.

Import Set Testing:

The first technical test is performed on the Import Set. The spreadsheet is uploaded and the imported source records are checked. The testing team verifies whether all spreadsheet columns are recognized correctly and whether the source data is loaded into the Import Set without unexpected changes.

Transform Map Testing:

The Transform Map is then tested to verify whether the source data is transferred correctly into the target ServiceNow table. The transformation process is executed using the prepared test data. The system's transform results are reviewed to identify successful, skipped, or failed records.

Field Mapping Validation:

Field mapping validation is an important part of testing. Each source spreadsheet column is compared with its corresponding target ServiceNow field. The testing team verifies that values such as names, descriptions, categories, priorities, dates, and other information are placed in the correct fields.

Transformation Rule Testing:

If transformation scripts or rules are configured, they must also be tested. The testing team verifies whether values are modified according to the defined requirements. For example, data formats may be converted, default values may be assigned, or reference values may be processed before the records are inserted into the target table.

Data Validation:

After the transformation is completed, the target records are compared with the original spreadsheet data. The team checks whether the records contain accurate and complete information. Mandatory fields, reference fields, data formats, and relationships are also validated to ensure that the imported records meet the required standards.
